

CMPT 476 Lecture 6

A few qubits more

Review complex numbers

What is the significance of a gate that cannot be written as the tensor product of two other gates?

- States $|q\rangle = \sum_i a_i |i\rangle = \begin{bmatrix} a_0 \\ \vdots \\ a_{d-1} \end{bmatrix} \in \mathbb{C}^d$ s.t. $\sum |a_i|^2 = 1$

- Measurement sends $|q\rangle$ to $|i\rangle$ with prob. $|a_i|^2$
- Gates send $|q\rangle \rightarrow U|q\rangle$ where $U \in \mathcal{L}(\mathbb{C}^d)$ is unitary ($U^\dagger = U^{-1} \iff U^\dagger U = U U^\dagger = I$) and has matrix $\sum_{i,j} U_{ij} |i\rangle \langle j|$, or

$$\begin{bmatrix} U_{00} & U_{01} & \cdots & U_{0d-1} \\ U_{10} & U_{11} & & \\ \vdots & & \ddots & \\ U_{d-10} & & & U_{d-1d-1} \end{bmatrix}$$

An example of a unitary on \mathbb{C}^4 is the CNOT gate from lecture 2

$$(\text{NOT} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix})$$

Today we will learn how to build **composite systems** like \mathbb{C}^4 from two qubits (i.e. \mathbb{C}^2), how to **operate** on them, and some **implications**.

- How does a 4-dimensional system arise? Could be
- An electron in one of 4 orbitals (is this even possible?)
 - A photon with a polarization and path
(\downarrow or \leftrightarrow) (\uparrow or \rightarrow)
 - Two physically separate qubits

If there is a polarization and path, can we think of it as two dimensions, where left, right, north, and south denote different aspects?

Are the four dimensions coming about from the two possible options with polarization and path?

Each of the above has 4 physical states, but drastically different dynamics. The last one in particular can only evolve according to local operations on either a qubit. We shall see that with entanglement, local operations have surprising power.

First, suppose Alice's qubit has state $|4\rangle = \alpha|0\rangle + \beta|1\rangle$ and Bob's has state $|4\rangle = \gamma|0\rangle + \delta|1\rangle$. If both Alice and Bob measure their qubits, what is the distribution of outcomes?

Assuming the qubits are not entangled.

- $|0\rangle$ and $|0\rangle \longrightarrow |\alpha|^2 \cdot |\gamma|^2$
- $|0\rangle$ and $|1\rangle \longrightarrow |\alpha|^2 \cdot |\delta|^2$
- $|1\rangle$ and $|0\rangle \longrightarrow |\beta|^2 \cdot |\gamma|^2$
- $|1\rangle$ and $|1\rangle \longrightarrow |\beta|^2 \cdot |\delta|^2$

We saw in lecture 2 that this is the joint prob. distribution

$$\begin{bmatrix} |\alpha|^2 \\ |\beta|^2 \end{bmatrix} \otimes \begin{bmatrix} |\gamma|^2 \\ |\delta|^2 \end{bmatrix} = \begin{bmatrix} |\alpha|^2|\gamma|^2 \\ |\alpha|^2|\delta|^2 \\ |\beta|^2|\gamma|^2 \\ |\beta|^2|\delta|^2 \end{bmatrix}$$

tensor product

Because the qubits are isolated, there is no interference.

If the qubits are entangled, can we have interference?

Thinking of quantum amplitudes as "probabilities" we can wonder if

$$\begin{bmatrix} \alpha \\ \beta \end{bmatrix} \otimes \begin{bmatrix} \gamma \\ \delta \end{bmatrix} = \begin{bmatrix} \alpha\gamma \\ \alpha\delta \\ \beta\gamma \\ \beta\delta \end{bmatrix}$$

is a sensible representation of the 4-dimensional state. Indeed, the expression $|\alpha\gamma|^2 + |\alpha\delta|^2 + |\beta\gamma|^2 + |\beta\delta|^2$ is one, so the entire expression evaluates to one.

$$|\alpha\gamma|^2 = |\alpha|^2|\gamma|^2 \Rightarrow |\alpha\gamma|^2 + |\alpha\delta|^2 + |\beta\gamma|^2 + |\beta\delta|^2 \\ = |\alpha|^2(|\gamma|^2 + |\delta|^2) + |\beta|^2(|\gamma|^2 + |\delta|^2) \\ = 1$$

~~Doesn't make sense~~

(State of a composite system, pt 1)

Given two systems in states $|1\rangle$ and $|0\rangle$, their joint state is $|1\rangle \otimes |0\rangle$

Assume Alice starts in the state $|+\rangle$ and Bob starts in $|0\rangle$. Going back to Alice and Bob, what if they brought their qubits together (i.e. $|1\rangle \otimes |0\rangle$) and then applied a CNOT to the joint state?

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} \alpha & \gamma \\ \beta & \delta \end{bmatrix} = \begin{bmatrix} \alpha & \gamma \\ \alpha & \delta \\ \beta & \delta \\ \beta & \delta \end{bmatrix}$$

Suppose $\alpha = \frac{1}{\sqrt{2}}$, $\beta = \frac{1}{\sqrt{2}}$, $\gamma = 1$, $\delta = 0$. Then

Compose the tensor product out of a linear combination of the $|0\rangle$ and $|1\rangle$ states and then apply the CNOT gate.

$$\begin{bmatrix} \alpha & \gamma \\ \beta & \delta \end{bmatrix} = \begin{bmatrix} \frac{1}{\sqrt{2}} \\ 0 \\ 0 \\ \frac{1}{\sqrt{2}} \end{bmatrix} \neq \begin{bmatrix} a \\ b \end{bmatrix} \otimes \begin{bmatrix} c \\ d \end{bmatrix} = \begin{bmatrix} ac \\ ad \\ bc \\ bd \end{bmatrix}$$

(Why?)

Recall that in a probabilistic setting we said that Alice & Bob's states are **correlated** if the joint state $|1\rangle \neq [a] \otimes [c]$. In **Quantum mechanics** we say their states are **entangled**. Since the above postulate says nothing about composite systems with **entangled** states, we need to generalize it a bit using more linear algebra.

Interference arrives after evolving the state.

When we look at the state, it is just looking at the vector.

(Tensor products)

Let V, W be two Vector spaces (e.g. Hilbert spaces)
 The tensor product $V \otimes W$ is a vector space such that:

$$1. \dim(V \otimes W) = \dim(V) \cdot \dim(W) \quad \text{Important.}$$

$$2. v \otimes w \in V \otimes W \quad \forall v \in V, w \in W$$

$$3. (v+u) \otimes w = v \otimes w + u \otimes w$$

$$4. v \otimes (u+w) = v \otimes u + v \otimes w$$

$$5. (cv) \otimes w = v \otimes (cw) = c(v \otimes w), \quad c \text{ scalar}$$

\otimes is
bilinear

Linear in either argument

The definition above describes tensor products abstractly (and is in fact missing a crucial abstract property). Since we work in finite dimensions it's easier to simply give a basis for $V \otimes W$

(Basis of $V \otimes W$)

orthonormal

Let $V & W$ be V.S. with bases $\{|e_i\rangle\}, \{|f_j\rangle\}$ respectively. Then $V \otimes W$ has an orthonormal basis

$$\{|e_i\rangle \otimes |f_j\rangle\} = \{|e_i\rangle |f_j\rangle\}$$

Is this since the tensor product of two states is the result of applying one linear combination of the first basis against another linear combination of the second basis, we have that the new basis is a linear combination of their

Ex.

$\mathbb{C}^2 \otimes \mathbb{C}^2$ has basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$

If $|4\rangle = i|11\rangle$ and $|\Psi\rangle = \frac{1}{\sqrt{5}}|00\rangle + \frac{2}{\sqrt{5}}|10\rangle$, then

$$|\Psi\rangle \otimes |4\rangle = i|11\rangle \otimes \left(\frac{1}{\sqrt{5}}|00\rangle + \frac{2}{\sqrt{5}}|10\rangle\right)$$

$$= \frac{i}{\sqrt{5}}|11|00\rangle + \frac{2i}{\sqrt{5}}|11|10\rangle$$

$|00\rangle$ = tensor-product($|0\rangle, |0\rangle$)

(Multi-qubit quantum computing & notation)

$\mathbb{C}^2 \otimes \mathbb{C}^2$ and \mathbb{C}^4 look very similar...

	$\mathbb{C}^2 \otimes \mathbb{C}^2$	\mathbb{C}^4
dim	$2 \times 2 = 4$	4
basis	$\{(00), (01), (10), (11)\}$ $\{(1100), (1101), (1110), (1111)\}$	$\{(00), (01), (10), (11)\}$ $\{(100), (101), (110), (111)\}$ Binary expansion

We say $\mathbb{C}^2 \otimes \mathbb{C}^2 \simeq \mathbb{C}^4$ via the isomorphism
 $|ij\rangle \leftrightarrow |ij\rangle$. In practice we view $\mathbb{C}^2 \otimes \mathbb{C}^2 = \mathbb{C}^4$
and write the following equivalently:

$$e_i = |i\rangle = |i, i_0\rangle = |i, \rangle |i_0\rangle = |i, \rangle \otimes |i_0\rangle$$

More generally, for n qubits,

$$\underbrace{\mathbb{C}^2 \otimes \cdots \otimes \mathbb{C}^2}_{n \text{ times}} \simeq \mathbb{C}^{2^n}$$

$$|i\rangle = |i_{n-1} \cdots i_0\rangle = |i_{n-1}\rangle \cdots |i_0\rangle = \begin{bmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{bmatrix} \leftarrow \text{ith entry}$$

And for n qudits of dimension d ,

$$\mathbb{C}^d \otimes \cdots \otimes \mathbb{C}^d \simeq \mathbb{C}^{d^n}$$

(More notation)

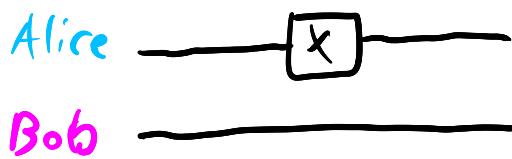

To make it even more confusing, depending on the context the following are the same

$$|1\rangle \otimes |2\rangle, |1\rangle |2\rangle, |1, 2\rangle$$

(local operations)

If there are local operations, are there global operations?

Back to our example, suppose Alice wants to apply a NOT/X gate to her qubit. Diagrammatically,

We haven't used circuit diagrams much yet because we only had 1 qubit. They'll factor in more now. Note that
 $\boxed{A} \otimes \boxed{B} = BA$
 since time flows left to right

If their states are not entangled we might view this circuit as sending

$$|1\rangle_A \otimes |0\rangle_B \rightarrow (X|1\rangle_A) \otimes |0\rangle_B$$

If they are entangled, we need a way of describing "X on Alice's qubit" as a linear operator over $C^2 \otimes C^2 \cong C^4$.

State of n qubits: superposition of n-bit strings
 superposition of n-bit strings != n bits in superposition

position, we have two amplitudes for each bit (one to measure the one and zero state), so

for n bits we have 2^n amplitudes

For a superposition of n-bit strings,

(Tensor product of operators)

Let $A: V \rightarrow V$, $B: W \rightarrow W$ be linear operators on V & W . Then $A \otimes B: V \otimes W \rightarrow V \otimes W$ is the linear operator defined by

$$(A \otimes B)|v\rangle \otimes |w\rangle = (Av) \otimes (Bw)$$

Ask Matt to clarify on why the transformation must be uniquely defined

As a matrix, this corresponds to

Barf!

$$\begin{bmatrix} A_{00} & A_{01} \\ A_{10} & A_{11} \end{bmatrix} \otimes \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix} = \begin{bmatrix} A_{00} \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix} & A_{01} \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix} \\ A_{10} \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix} & A_{11} \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix} \end{bmatrix}$$

of two states, it represented the joint probability of two states.
 does not have the significance of a joint probability.

Ex.

Recall that $X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$, $Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$.

Compute:

$$1. X \otimes I = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \otimes \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

$$2. I \otimes X = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \otimes \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

$$3. Z \otimes Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \otimes \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$4. (X \otimes I)(|0\rangle\langle 1|) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} = |1\rangle\langle 1|$$

(Properties of tensor products)

$$1. s(A \otimes B) = sA \otimes B = A \otimes sB$$

$$2. (A+B) \otimes C = A \otimes C + B \otimes C \quad (\text{left distributive})$$

$$3. A \otimes (B+C) = A \otimes B + A \otimes C \quad (\text{right distributive})$$

$$4. A \otimes (B \otimes C) = (A \otimes B) \otimes C \quad (\text{associative})$$

$$5. (A \otimes B)^+ = A^+ \otimes B^+ \quad (+-\text{distributivity})$$

$$6. (A \otimes B)(C \otimes D) = AC \otimes BD \quad (\text{bi-functor})$$

dagger, not plus.

Ex. $(|1\rangle\langle 1|)(|0\rangle\langle 1|) + (|0\rangle\langle 1|)(|1\rangle\langle 0|) - (|1\rangle\langle 0|)(|0\rangle\langle 0|)$

I thought the tensor products of 1 and 0 would cancel out.

$$= (|1\rangle\langle 1|)(|0\rangle\langle 1|) - (|1\rangle\langle 0|)(|0\rangle\langle 0|) \quad (+-\text{st.})$$

$$= (|1\rangle\langle 1|)(|0\rangle\langle 1|) - (|1\rangle\langle 1|)(|0\rangle\langle 0|) \quad (\text{dist.})$$

$$= (|1\rangle\langle 1|) - (|1\rangle\langle 1|) \quad (\text{bi-func})$$

$$= -1 \quad (\text{surprised?})$$

(Back to our friends)

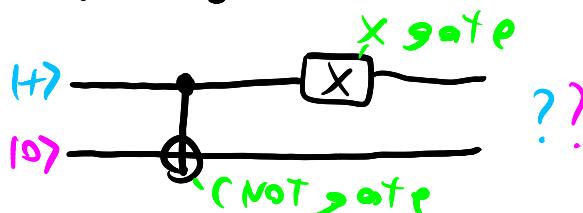

We now have all the ingredients to compute the final state of our Alice and Bob example. To recap:

1. Alice starts in state $\frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) = |+\rangle$,
Bob in state $|0\rangle$

2. Alice and Bob jointly apply CNOT

3. Alice separates her qubit and applies X

We can write this as a **Circuit**

Recalling that $\text{CNOT} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$, $X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, the

final state is

$$\left(\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \otimes \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \left(\frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \otimes \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right)$$

$$= \frac{1}{\sqrt{2}} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{\sqrt{2}} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{\sqrt{2}} \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}$$

$$= \frac{1}{\sqrt{2}} (|01\rangle + |10\rangle)$$

Alt. calculation

$$|00\rangle \xrightarrow{\text{CNOT}} |00\rangle$$

$$\text{CNOT}: |01\rangle \xrightarrow{\text{CNOT}} |10\rangle$$

For the meaning of this tensor product, it seems that either the first interpretation
1: apply cnot and return the current vector
2: return the current vector after applying cnot
seem the same.

Is there an effect from swapping the order?

I thought a linear combination of operators would act on the corresponding vectors.
Why is it that the X gate is applied on both vectors?

SO

$$(X \otimes I) \text{CNOT} \left(\frac{1}{\sqrt{2}} |00\rangle + \frac{1}{\sqrt{2}} |11\rangle \right)$$

$$= (X \otimes I) \left(\frac{1}{\sqrt{2}} |00\rangle + \frac{1}{\sqrt{2}} |11\rangle \right)$$

How does this work if the X gate is defined for a $\frac{1}{\sqrt{2}}$ vector?

Is there a version of the X gate made for 4×1 matrices?

Dirac is best 😊

(Is quantum computing stochastic?)

Measurement statistics in the Alice and Bob example are identical whether we measure first and proceed stochastically, taking

$$\frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \end{bmatrix} \xrightarrow{\text{measure}} \frac{1}{2} \begin{bmatrix} 1 \\ 0 \\ 1 \\ 0 \end{bmatrix}$$

We might wonder if all QC can be modeled by stochastic matrices. The answer lies in the hadamard gate

$$H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

which has the measurement statistics of a coin flip:

$$H|0\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle) \xrightarrow{\text{measure}} \frac{1}{2} \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

However, unlike a classical coin flip

$$\frac{1}{2} \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

flipping the coin again gets us back to the original state:

$$H\left(\frac{1}{\sqrt{2}}|0\rangle + \frac{1}{\sqrt{2}}|1\rangle\right) = |0\rangle \xrightarrow{\text{measure}} \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

In contrast,

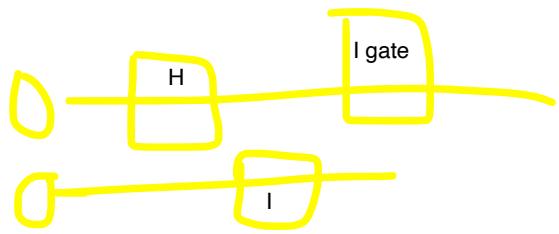

Can we have a negative amplitude?

Whenever we saw amplitudes, they always had a non-negative magnitude by taking their absolute value.

What does negative mean here?

What does positive amplitude mean?

The reason is negative amplitudes giving rise to interference. We will examine this and other quantum effects in the coming weeks.

When you do (H tensor-prod I), you are applying the hadamard gate to the first quibit.

-prod X) CNOT(H tensor-prod I)

Easier way:

each computation on the basis vectors

EX:

sor-prod X)CNOT(H tensor-prod I)|00>

If we measure a four dimensional system in the computational basis where the quibits are separated,

here is no way to assure that measuring a four dimensional system can be done at the same time by multiple people.
