Question 1 [3 points]: A universal classical gate

The NAND gate is a classical gate with the following truth table:

1. Show that the NOT gate can be implemented with NAND gates and FANOUT. You may draw a circuit or simply give the algebraic expression.

e implementations using a truth table? Show that the gate set $\{NAND, FANOUT\}$ is universal for classical computation by giving implementations of each gate in the universal gate set $\{AND, OR, NOT, FANOUT\}$.

Question 2 [6 points]: Dirac notation

Let $|\psi\rangle=\frac{1}{\sqrt{3}}|0\rangle+\frac{i}{\sqrt{3}}|1\rangle+\frac{-1}{\sqrt{3}}|2\rangle,\ |\phi\rangle=\frac{1}{\sqrt{2}}|1\rangle+\frac{-i}{\sqrt{2}}|2\rangle$ be two states of a **qutrit** (i.e. a three-level or three-dimensional system).

- 1. Give the explicit column vectors of $|\psi\rangle$ and $|\phi\rangle$ v = 1/sqrt(3) [1 0 0] + i/sqrt(3)[0 1 0] -1/sqrt(3)[0 0 1]
- 2. Calculate the following:

- $\langle \psi | \psi \rangle$
- $\langle \phi | \phi \rangle$

v =

- $\langle \psi | \phi \rangle$
- $|\psi\rangle\langle\phi|$
- $|\psi\rangle\otimes|\phi\rangle$
- 3. Is the vector $|\psi\rangle + |\phi\rangle$ a unit vector? If not, normalize it to get a unit vector.

Probability of receiving 1 or 0 is both 1/2 Question 3 [4 points]: Gates and measurement

Suppose we have a qubit initially in the state $\frac{1}{\sqrt{2}}|0\rangle + \frac{e^{i\theta}}{\sqrt{2}}|1\rangle$ for some $\theta \in \mathbb{R}$.

- 1. Calculate the probabilities of receiving result "0" or "1" if the qubit is measured.
- 2. Resalting definition of the Hadamard gate, which has the vectors $|+\rangle$ and $|-\rangle$ as its columns:

= 1/sqrt(2)[(10> + 11>) + (10> - 11>)]
$$H = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

If we first apply the Hadamard gate to the initial state $\frac{1}{\sqrt{2}}|0\rangle + \frac{e^{i\theta}}{\sqrt{2}}|1\rangle$ and then measure, what are the probabilities of receiving the "0" and "1" results as an function of θ ? Note: this is the same thing as measuring the initial state in the $|+\rangle$, $|-\rangle$ basis.

Question 4 [5 points]: Eigenvectors

Recall that an eigenvector of a matrix A is a vector $|v\rangle$ such that $A|v\rangle = \lambda |v\rangle$ for some scalar eigenvalue λ .

1. Let $Y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}$. Find two **unit** vectors $|+_Y\rangle$, $|-_Y\rangle$ such that

$$Y|+_Y\rangle = |+_Y\rangle$$

 $Y|-_Y\rangle = -|-_Y\rangle$

- 2. Let U be the 2 by 2 matrix with columns $|+_Y\rangle$ and $|-_Y\rangle$. Is U unitary?
- 3. Calculate $U^{\dagger}YU$.

If theta is 0, then I get probabilities which do not sum to 1.

If I take the absolute value of 1/2 - (e^(itheta))/2, I still end up with the same values when squaring the expression even if the difference between the two values is negative and I must negate the expression.

Ask the professor about this.
